Host a Website on Amazon S3

Aman gangwar

Introducing Today's Project!

In this project, we will demonstrate how to use S3 to host a static website . We are doing this project to learn about AWS and cloud services and how they can be used to store objects in the cloud and even host websites (how does they work ?!)

Tools and concepts

Services we used were Amazon S3.Key concepts we learn include bucket policies,uploading static website files ,index.html, bucket endpoint URLs and ACLs and how they control access to our bucket objects.

Project reflection

This project took me approximately 1.5 hours.The most challenging part was resolving 403 Forbidden error. It was most rewarding to our webpage load live and be public to world.

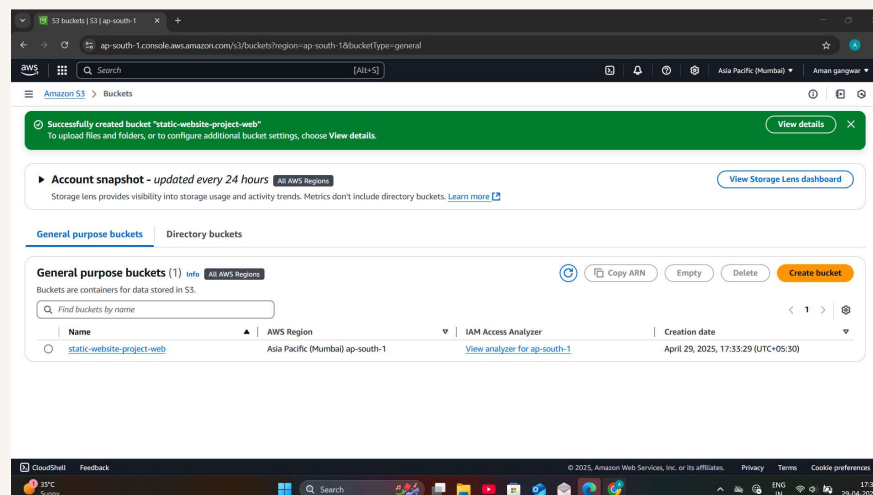

How I Set Up an S3 Bucket

Creating an S3 bucket took us less than 5 minutes

The Region I picked for my S3 bucket was Mumbai because it's closest to us. It lowers the time to retrieve your things (means low latency).

S3 bucket names are globally unique! This means no two S3 buckets in the entire world can have the same name.

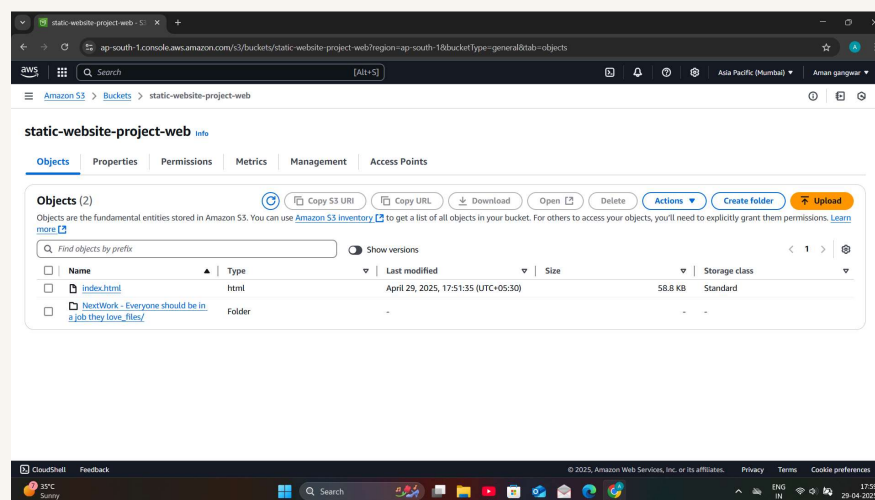

Upload Website Files to S3

index.html and image assets

I uploaded two files to my S3 bucket - they were an index.html file (this determine the structure i.e. what goes inside your website) and a folder of images and assets (this will fill in the website with images and things will look at)

Both files are necessary for this project as index.html determines structure but the structure alone does not illustrate the content of the website. ie. if index.html says "insert images here", it might not have the actual image to display.

Static Website Hosting on S3

Website hosting means putting our website file on a web server designed to turn the files into a website page that people can visit.

To enable website hosting with my S3 bucket, we went into the properties tab of our bucket ,enabled static website hosting and we also labelled "index.html" as our index document i.e. this is the document that we're trying to host.

An ACL is a way to configure permission setting inside a bucket .We enabled ACLs so that we can control access to our website files later.

For your customers to access content at the website endpoint, you must make all your content publicly readable. [Using Amazon S3 Block Public Access](#)

Bucket Endpoints

Once static website is enabled, S3 produces a bucket endpoint URL, which is a URL that takes you to the website that you've

We saw a 403 forbidden error! because objects in a bucket are public by default- even though we have switched off "Block all Public Access", the website files themselves are still completely private. They need to be public files too

403 Forbidden

- Code: AccessDenied
- Message: Access Denied
- RequestId: 6TBR8F10RQW7KTGG
- HostId: oS4Dw4g0Ftr0t5ZLhzdBHf493scFTB3a5kkqSyePb47nktAeLEbng2BYYVdeeypcXz4avCpF7s=

Success!

To resolve this 403 Forbidden error, we updated the access setting of the files inside our bucket too. Using ACLs, we made our bucket files public! Once we checked our S3 endpoint, we see a webpage all loaded up:)
